

1. Description

In a waste water treatment network, it is necessary to take samples to measure effluent pollutant levels. For this purpose, a portable, battery-powered sampler may be used to store samples episodically.

Some types of Data Logger (LT42, LT-US, LT-Radar) are able to drive a sampler.

2 operating modes are available:

- **Sampler (time control):** upon the appearance of logic data (DI or Threshold), the user defines the sampling period (3, 5, 10, 15, 30 or 60 minutes). For example, during an overflow, or when a high-level threshold is exceeded, to perform sampling every 10 minutes.
- **Sampler (volume control):** each time a volume of effluents has been discharged, a sample is taken; the volume is calculated based on the predefined "AI – Flow 1" conversion table.

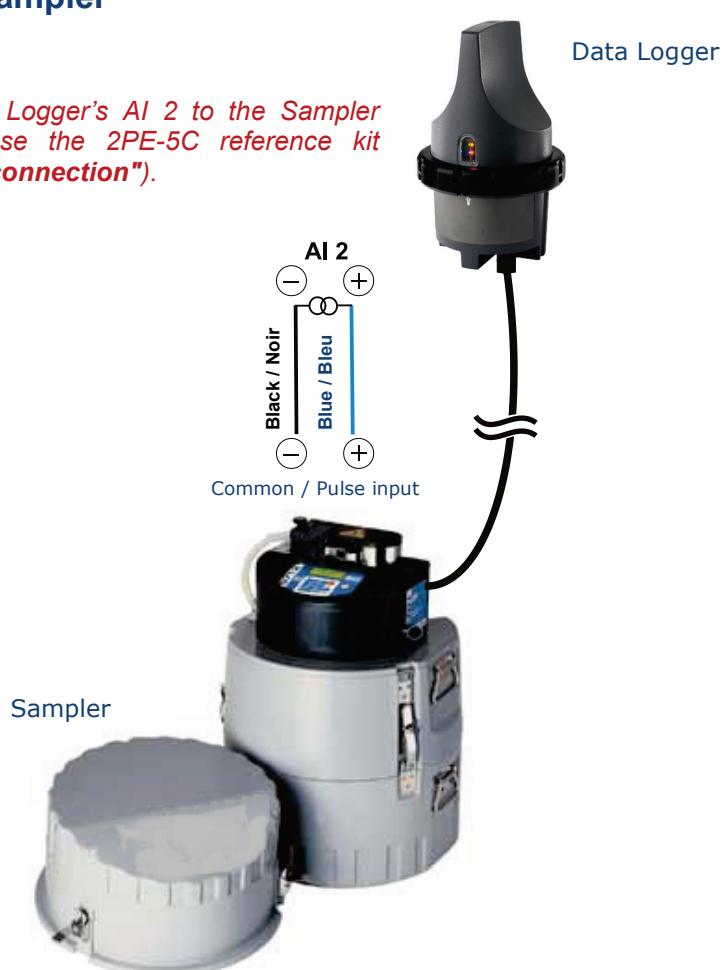

Example of use case with LT-Radar: Automatically trigger a sampling in case of overflow (in stormy weather) to analyse the rejects afterwards.

2. Installation

2.1. Connection of the Sampler

Connection of the Data Logger's AI 2 to the Sampler must be waterproof. Use the 2PE-5C reference kit (see § "IP68 watertight connection").

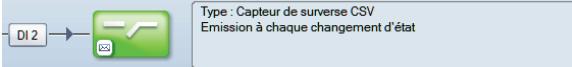

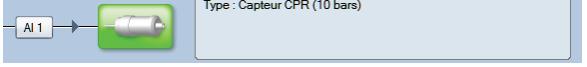

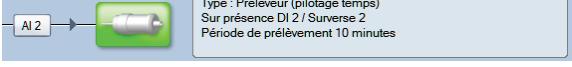

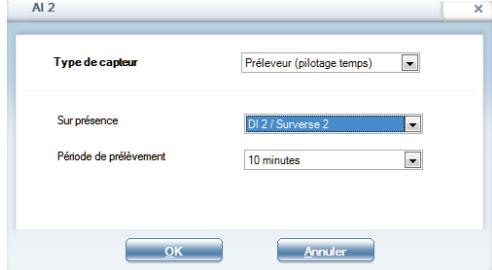

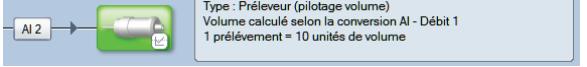

3. Settings

3.1. Configuration of the Sampler

On the AI 2, the Data Logger generates a 12V / 150ms pulse; it is necessary to configure the Sampler to take a **sample on each pulse**.

3.2. Configuration of the Data Logger

With SOFTTOOLS, it is necessary to configure:

Sampler (time control)	Sampler (volume control)
<p>1 A DI, a threshold, or overflow information for sampling on appearance of a logical datum</p> 	<p>1 A level measurement (AI 1 or LT-US measurement)</p> 
<p>2 The AI 2 for control of the sampler (time control) upon presence of a logical datum and definition of the sampling period</p>  	<p>2 A "Height / Flow" conversion table for calculation of the volume (via the "Treatments" tab)</p>  

3.3. Connection – Installation

The AI 2 information shows the total number of samples taken. The user may perform a "Sampler test" by triggering a sampling operation, which will reset this total number.
